TPO (Thyroid Peroxidas) Antibody ELISA Kit

Cat. No.:DEIA1894
Pkg.Size:96T

Intended use

For Quantitative Determination of Thyroid Peroxidase (TPO) Autoantibodies in Human Serum or Plasma by a Microplate Enzyme Immunoassay. Measurements of TPO autoantibodies may aid in the diagnosis of certain thyroid diseases such as Hashimoto’s and Grave’s as well as nontoxic goiter.

General Description

Antibodies to thyroid peroxidase have been shown to be characteristically present from patients with Hashimoto thyroiditis (95%), idiopathic myedema (90%) and Graves Disease (80%). In fact 72% of patients positive for anti-TPO exhibit some degree of thyroid dysfunction. This has lead to the clinical measurement becoming a valuable tool in the diagnosis of thyroid dysfunction.

Measurements of antibodies to TPO have been done, in the past, by Passive Hemaglutination (PHA). PHA tests do not have the sensitivity of enzyme immunoassay and are limited by subjective interpretation. This procedure, with the enhanced sensitivity of EIA, permits the detectability of subclinical levels of antibodies to TPO. In addition, the results are quantitated by a spectrophotometer, which eliminates subjective interpretation.

The microplate enzyme immunoassay methodology provides the technician with optimum sensitivity while requiring few technical manipulations. In this method, serum reference, diluted patient specimen, or control is first added to a microplate well. Biotinylated Thyroid Peroxidase Antigen (TPO) is added, and then the reactants are mixed. Reaction results between the autoantibodies to TPO and the biotinylated TPO to form an immune complex, which is deposited to the surface of streptavidin coated wells through the high affinity reaction of biotin and streptavidin. After the completion of the required incubation period, aspiration or decantation separates the reactants that are not attached to the wells. An enzyme anti-human IgG conjugate is then added to permit quantitation of reaction through interacting with human IgG of the immune complex. After washing, the enzyme activity is determined by reaction with substrate to produce color.

The employment of several serum references of known antibody activity permits construction of a graph of enzyme and antibody activities. From comparison to the dose response curve, an unknown specimen’s enzyme activity can be correlated with autoimmune antibody level.

Principle Of The Test

The reagents required for the sequential ELISA assay include immobilized antigen, circulating autoantibody and enzyme-linked species-specific antibody. In this procedure, the immobilization takes place during the assay at the surface of a microplate well through the interaction of streptavidin coated on the well and exogenous added biotinylated thyroid peroxidase antigen. Upon mixing biotinylated antigen and a serum containing the autoantibody, a reaction results between the antigen and the antibody to form an immune-complex. Simultaneously, the complex is deposited to the well through the high affinity reaction of streptavidin and biotinylated antigen. After the incubation time, the well is washed to separate the unbound components by aspiration and/or decantation. The enzyme linked species-specific antibody (anti-h-IgG) is then added to the microwells. This conjugate binds to the immune complex that formed. The anti-h-IgG enzyme conjugate that binds to the immune complex in a second incubation is separated from unreacted material by a wash step. The enzyme activity in this fraction is directly proportional to the antibody concentration in the specimen. By utilizing several different serum references of known antibody activity, a reference curve can be generated from which the antibody activity of an unknown can be ascertained.
Reagents And Materials Provided

A. x-TPO Calibrators – 1.0 ml/vial, A-F
Six vials of references for anti-TPO at levels of 0(A), 25(B), 50(C), 100(D), 250(E) and 500(F) IU/ml. Store at 2-8°C. A preservative has been added. Note: The calibrators, human serum based, were calibrated using a reference preparation, which was assayed against the Medical Research Council (MRC) International Standard 66/387 for anti thyroid microsome.

B. TPO Biotin Reagent – 13 ml/vial
One vial of biotinylated thyroid peroxidase antigen stabilized in a buffering matrix. A preservative has been added. Store at 2-8°C.

C. Anti-TPO Enzyme-antigen Reagent – 13 ml/vial
One vial of anti-human IgG-horseradish peroxidase (HRP) conjugate stabilized in a buffering matrix. A preservative has been added. Store at 2-8°C.

D. Streptavidin Coated Microplate – 96 wells
One 96-well microplate coated with streptavidin and packaged in an aluminum bag with a drying agent. Store at 2-8°C.

E. Serum Diluent – 20 ml
One vial of serum diluent containing buffer salts and yellow dye. Store at 2-8°C.

F. Wash Solution Concentrate – 20 ml
One vial containing a surfactant in buffered saline. A preservative has been added. Store at 2-8°C.

G. Substrate A – 7 ml/vial
One bottle containing tetramethylbenzidine (TMB) in buffer. Store at 2-8°C.

H. Substrate B – 7 ml/vial
One bottle containing hydrogen peroxide (H2O2) in buffer. Store at 2-8°C.

I. Stop Solution – 8 ml/vial
One bottle containing a strong acid (1N HCl). Store at 2-8°C.

J. Product Instructions

Note 1: Do not use reagents beyond the kit expiration date.
Note 2: Opened reagents are stable for sixty days when stored at 2-8°C.
Note 3: Above reagents are for a single 96-well microplate.

Materials Required But Not Supplied

1. Pipette capable of delivering 10, 25 and 50 µl volumes with a precision of better than 1.5%.
2. Dispenser(s) for repetitive deliveries of 0.100 ml and 0.300 ml volumes with a precision of better than 1.5%.
3. Microplate washers or a squeeze bottle (optional).
4. Microplate Reader with 450 nm and 620 nm wavelength absorbance capability.
5. Absorbent Paper for blotting the microplate wells.
6. Plastic wrap or microplate cover for incubation steps.
7. Vacuum aspirator (optional) for wash steps.
8. Test tubes for patient dilution.
10. Quality control materials.

Specimen Collection And Handling

The specimens shall be blood; serum or plasma in type and the usual precautions in the collection of venipuncture samples should be observed.

For accurate comparison to established normal values, a fasting morning serum sample should be obtained. The blood should
be collected in a plain redtop venipuncture tube without additives or anti-coagulants (for serum) or evacuated tube(s) containing EDTA or heparin. Allow the blood to clot for serum samples. Centrifuge the specimen to separate the serum or plasma from the cells.

Samples may be refrigerated at 2-8°C for a maximum period of five days. If the specimen(s) cannot be assayed within this time, the sample(s) may be stored at temperatures of -20°C for up to 30 days. Avoid repetitive freezing and thawing.

When assayed in duplicate, 0.05 ml of the specimen is required.

### Reagent Preparation

1. **Serum Diluent**
   Dilute the serum diluent to 200 ml in a suitable container with distilled or deionized water.
   Store at 2-8°C.

2. **Wash Buffer**
   Dilute contents of wash concentrate to 1000 ml with distilled or deionized water in a suitable storage container.
   Store at room temperature 20-27°C for up to 60 days.

3. **Working Substrate Solution**
   Pour the contents of the amber vial labeled Solution ‘A’ into the clear vial labeled Solution ‘B’. Place the yellow cap on the clear vial for easy identification.
   Mix and label accordingly, store at 2-8°C.
   Note: Do not use the working substrate if it looks blue.

4. **Patient Sample Dilution (1/100)**
   Dispense 0.010 ml (10µl) of each patient specimen into 1 ml of serum diluent. Cover and vortex or mix thoroughly by inversion.
   Store at 2-8°C for up to forty-eight hours.

### Assay Steps

Before proceeding with the assay, bring all reagents, serum references and controls to room temperature (20-27°C).

1. Format the microplates’ wells for each serum reference, control and patient specimen to be assayed in duplicate. Replace any unused microwell strips back into the aluminum bag, seal and store at 2-8°C.
2. Pipette 0.025 ml (25µl) of the appropriate serum reference, control or diluted patient specimen into the assigned well.
3. Add 0.100 ml (100 µl) of TPO Biotin Reagent.
4. Swirl the microplate gently for 20-30 seconds to mix and cover.
5. Incubate 60 minutes at room temperature.
6. Discard the contents of the microplate by decantation or aspiration. If decanting, blot the plate dry with absorbent paper.
7. Add 350 µl of wash buffer (see Reagent Preparation Section), decant (blot and tap) or aspirate. Repeat two additional times for a total of three washes.
   An automatic or manual plate washer can be used. Follow the manufacturer’s instruction for proper usage. If a squeeze bottle is employed, fill each well by depressing the container (avoiding air bubbles) to dispense the wash.
   Decant the wash and repeat two additional times.
8. Add 0.100 ml (100 µl) of the x-TPO Enzyme Reagent to all wells.
   Always add reagents in the same order to minimize reaction time differences between wells.
   **DO NOT SHAKE THE PLATE AFTER ENZYME ADDITION.**
9. Incubate for thirty minutes at room temperature.
10. Repeat steps (6 & 7) as explained above.
11. Add 0.100 ml (100 µl) of Working Substrate Solution to all wells (see Reagent Preparation Section).
   Always add reagents in the same order to minimize reaction time differences between wells.
   **DO NOT SHAKE THE PLATE AFTER SUBSTRATE ADDITION.**
12. Incubate at room temperature for fifteen minutes.
13. Add 0.050 ml (50 µl) of stop solution to each well and mix gently for 15-20 seconds.
Always add reagents in the same order to minimize reaction time differences between wells.
14. Read the absorbance in each well at 450 nm (using a reference wavelength of 620-630 nm to minimize well imperfections) in a microplate reader.
The results should be read within thirty minutes of adding the stop solution.
Note: For re-assaying specimens with concentrations greater than 500 IU/ml, dilute the sample an additional 1:5 or 1:10 using the original diluted material. Multiply by the dilution factor to obtain the concentration of the specimen.

**Quality Control**

Each laboratory should assay controls at levels in the normal, borderline and elevated range for monitoring assay performance. These controls should be treated as unknowns and values determined in every test procedure performed. Quality control charts should be maintained to follow the performance of the supplied reagents. Pertinent statistical methods should be employed to ascertain trends.
The individual laboratory should set acceptable assay performance limits. In addition maximum absorbance should be consistent with past experience.
Significant deviation from established performance can indicate unnoticed change in experimental conditions or degradation of kit reagents. Fresh reagents should be used to determine the reason for the variations.

**Calculation**

A reference curve is used to ascertain the concentration of anti-TPO in unknown specimens.
1. Record the absorbance obtained from the printout of the microplate reader.
2. Plot the absorbance for each duplicate serum reference versus the corresponding anti-TPO activity in IU/ml on linear graph paper.
3. Draw the best-fit curve through the plotted points.
4. To determine the level of anti-TPO activity for an unknown, locate the average absorbance of the duplicates for each unknown on the vertical axis of the graph, find the intersecting point on the curve, and read the concentration (in IU/ml) from the horizontal axis of the graph (the duplicates of the unknown may be averaged as indicated).
Note: Computer Data reduction software designed for IEMA (ELISA) assays may also be used for the data reduction.

**Q.C. PARAMETERS**

In order for the assay results to be considered valid the following criteria should be met:
1. The absorbance (OD) of calibrator F should be ≥ 1.3.
2. Four out of six quality control pools should be within the established ranges.

**Typical Standard Curve**

These data are intended for illustration only and should not be used to calculate results from another run.
Reference Values

A study of normal population was undertaken to determine expected values for the Anti-TPO ELISA Test System. The number (n), mean (x) and standard deviation (σ) are given in Table below.

Values in excess of 40 IU/ml are considered positive for the presence of anti-TPO autoantibodies.

It is important to keep in mind that establishment of a range of values which can be expected to be found by a given method for a population of "normal"-persons is dependent upon a multiplicity of factors: the specificity of the method, the population tested and the precision of the method in the hands of the analyst. For these reasons each laboratory should depend upon the range of expected values established by the Manufacturer only until an in-house range can be determined by the analysts using the method with a population indigenous to the area in which the laboratory is located.

**Interpretation of Results**

1. Laboratory results alone are only one aspect for determining patient care and should not be the sole basis for therapy, particularly if the results conflict with other determinants.
2. For valid test results, adequate controls and other parameters must be within the listed ranges and assay requirements.
3. If test kits are altered, such as by mixing parts of different kits, which could produce false test results, or if results are incorrectly interpreted.
4. If computer controlled data reduction is used to interpret the results of the test, it is imperative that the predicted values for the calibrators fall within 10% of the assigned concentrations.
5. The presence of autoantibodies to TPO is confirmed when the serum level exceeds 40 IU/ml. The clinical significance of the result, coupled with anti-thyroglobulin activity, should be used in evaluating the thyroid condition. However, clinical inferences should not be solely based on this test but rather as an adjunct to the clinical manifestations of the patient and other relevant tests.

**Sensitivity**

The TPO (Thyroid Peroxidas) Antibody ELISA Kit has a sensitivity of 1.5 IU/ml.

**Specificity**

Interferences from ANA, DNA, thyroglobulin (Tg) and rheumatoid antibodies were found to be insignificant.

**Accuracy**

The TPO Ab ELISA was compared with a reference microplate anti-TPO ELISA. Biological specimens from normal and disease states populations were used. The disease states included; Hashimoto’s thyroiditis, Graves Disease, thyroid nodules as well as thyroid carcinoma. The total number of such specimens was 82. The least square regression equation and the correlation coefficient were computed for the anti-TPO ELISA method in comparison with the reference method.

**Reproducibility**

The within and between assay precision of the TPO Ab ELISA Test System were determined by analyses on three different levels of pool control sera. The number (N), mean (X), standard deviation (σ) and coefficient of variation (C.V.) for each of these control sera are presented in Table 2 and Table 3.
Precautions

Not for Internal or External Use in Humans or Animals.

All products that contain human serum have been found to be non-reactive for Hepatitis B Surface Antigen, HIV 1&2 and HCV Antibodies by FDA licensed reagents. Since no known test can offer complete assurance that infectious agents are absent, all human serum products should be handled as potentially hazardous and capable of transmitting disease. Good laboratory procedures for handling blood products can be found in the Center for Disease Control / National Institute of Health, "Biosafety in Microbiological and Biomedical Laboratories," 2nd Edition, 1988, HHS Publication No. (CDC) 88-8395.
